1. Electron Modeling

In this part of the assignment, a simple Matlab program is written to model the electrons as particles with a simplistic Monte-Carlo model using the following values [1]:

• Rest mass: $m_o = 9.1093837015 \times 10^{-31} \ KG$

• Effective mass of electrons: $m_n = 0.26m_0$

• Normal size of the region: $200 \text{nm} \times 100 \text{nm}$

• Boltzmann constant: $K = 1.38064852 \times 10^{-23} \ J \cdot K^{-1}$

• Temperature: 300K

The codes for part 1 are in the folder named "Q1", which contains the following files:

- AddElectrons.m –Function that adds electrons randomly in the region
- globalVars.m File that groups the constants used in the simulation
- MD_Q1.m Entry point script for the simulation for part 1
- PlotPoint.m Function that plots the trajectories of the electrons
- tempDisplay.m Function that displays the temperature map
- 1. What is the thermal velocity v_{th} ? Assume $T = 300 \,\mathrm{K}$.

The thermal velocity V_{th} can be calculated using the following equations:

$$\because \frac{1}{2} m v_{th}^2 = \frac{2}{2} KT$$

$$\therefore v_{th} = \sqrt{\frac{2kT}{m}} = 187019.1244 \ m/s$$

2. If the mean time between collisions is $\tau_{mn} = 0.2 \,\mathrm{ps}$ what is the mean free path?

If the mean time between collisions is $\tau_{mn} = 0.2 \ ps$, the mean free path (MFP) can be calculated as follow:

$$MFP = v_{th} \times \tau_{mn} = 3.7404 \times 10^{-8} \, m$$

```
% Initialize the mean time between collision
Tmn = 0.2e-12; % 0.2ps
d = Tmn*vth; % Calculate the mean free path
display("Mean path is "+ d);

>> MD_Q1
    "vth = 187019.1244"

"Mean path is 3.7404e-08"
```

- 3. Write a program that will model the random motion of the electrons. The program should do the following:
- Assign each particle a random location in the x-y plane within the region defined by the extent of the Silicon. For simplicity you may use a small number of particles (1000-10000 works well) but you can start much smaller initially if you like.
- Assign each particle a random location in the x-y plane within the region defined by the extent of the Silicon. For simplicity you may use a small number of particles (1000-10000 works well) but you can start much smaller initially if you like.
- Assign each particle with the fixed velocity given by v_{th} but give each one a random direction. To do this pick a random direction ϕ and generate v_x and v_y . Later you will generate these from the Maxwell-Boltzmann distributions.

For this part, a function named "AddElectrons()" is programmed to add electrons in a given region randomly.

```
MD_Q1.m × AddElectrons.m × +
       % This function add a bunch of electrons in a given region randomly for Q1
1 -
 2
       % @param numE = number of electrons
                region = region for the electrons
 3
                vth = magnitude of the velocity
 4
 5
       function AddElectrons(numE, region, vth)
       global C % Constants
 6
 7
       global x y % arrays for current electron positions
 8
       global xp yp % arrays for previous electron positions
9
       global vx vy % arrays for current electron velocities
10
       % Create the arrays for electrons locations
11
       x = rand(1, numE) * region.x;
12
13
       xp = x;
       y = rand(1, numE) * region.y;
14
15
       yp = y;
16
       % Create a helper array for electrons directions
17
18
       phi = rand(1, numE) * 2*pi;
19
       % Create the arrays for current electron velocities
20
       vx = vth .* cos(phi);
21
22
       vy = vth .* sin(phi);
23
24
       end
```

• At a fixed time interval of $\triangle t$, update the particle location using Newton's laws of motion. You will need to pick a time step size that takes into account the velocity of your particles and the size of the region. Typically the spacial step should be smaller than 1/100 of the region size. Simulate for nominally 1000 timesteps. This should allow each particle to bounce around quite a bit inside the region.

For this part, a variable was created to store the fixed time interval Δt .

The simulation loop was programmed to update the particle location using Newton's laws of motion.

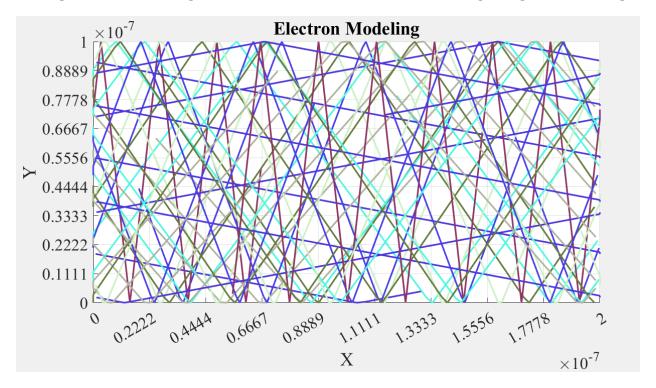

```
MD_Q1.m ×
            +
          % Loop for simulation
61
          for iSim = 1:numSim
62
               PlotPoint(numEPlot, numGridX, numGridY);
63
64
65
               % Store the current positions
66
               xp = x;
67
               yp = y;
               % Calculate the future positions: x = x0 + vx*t
68
69
               x = x + vx * deltaT;
70
               y = y + vy * deltaT;
```

• For a few of the particles trace out their trajectories using the 'plot' command in Matlab. To plot the trajectories you should keep the previous x and y positions. Hint: use breakpoints to step through the trajectory and see what is "going on"; use the 'pause' command in Matlab to have the plot update in a loop.

To plot the trajectories of the particles, a function named "PlotPoint()" is programmed.

```
MD_Q1.m × PlotPoint.m × +
      % Helper function to plot one point for electron position
1 -
      % @param
                numEPlot = number of electrons to be plotted
2
                numGridX = number of grid on the x axis
3
                numGridY = number of grid on the y axis
4
      function PlotPoint(numEPlot, numGridX, numGridY)
5
6
      global x y xp yp limits
7
8
      % plot the electron positions
9
      plot([xp(1:numEPlot);x(1:numEPlot)], [yp(1:numEPlot);y(1:numEPlot)])
```

• Show a 2-D plot of all (or a subset) of the particles that updates with each time step. *Hint: use the 'pause' command in Matlab to have the plot update in a loop.*

- For the y direction use a boundary condition where the particle reflects at the same angle (specular) and retains its velocity.
- For the x direction use a periodic boundary condition where the particle jumps to the opposite edge. i.e. if it reaches the right side it appears at the left with the same velocity.

The logic for boundary condition was implemented with if statements inside the simulation loop.

```
MD_Q1.m ×
              % Loop through all the particles
72
              for iE=1:numE
73
                  % flag for invalid
74
                  bInvalid = false;
75
                  % Check for invalid x position
76
                  if x(iE) < 0
77
                      x(iE) = Region.x; % Appear on right
78
                      xp(iE) = x(iE);
79
                      bInvalid = true;
80
                  elseif x(iE) > Region.x
81
                      x(iE) = 0; % Appear on left
82
                      xp(iE) = x(iE);
83
                      bInvalid = true;
84
                  end
85
```

```
% Check for invalid y position
86
                  if y(iE) < 0
87
                      y(iE) = 0; % Reflect
88
                      vy(iE) = -vy(iE);
89
                       bInvalid = true;
90
                  elseif y(iE) > Region.y
91
                      y(iE) = Region.y; % Reflect
92
                       vy(iE) = -vy(iE);
93
                       bInvalid = true;
94
                  end
95
96
              end
```

• Calculate and display the semiconductor temperature on the plot at a fixed time interval and verify that it stays constant.

An array was created to hold the temperature to calculate the temperature over time.

Inside the simulation loop, the temperature was calculated and stored in the array.

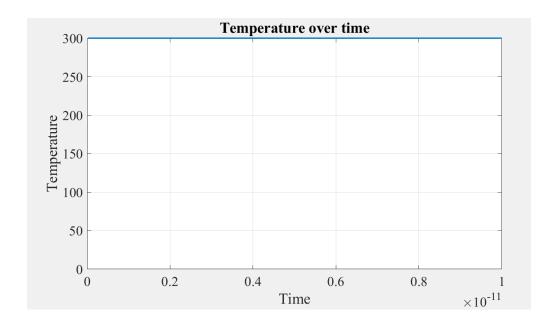

```
MD_Q1.m * +

% Calculate the current average temperature
vth2_mean = mean(sqrt(vx.^2+vy.^2)).^2;
tempOverTime(iSim) = C.mn*vth2_mean/(2*C.kb);
```

After the simulation loop, the temperature over time is plotted using the following code.

```
MD_Q1.m ×
           % Plot average temperature over time
111
112
           figure(4)
113
           plot(deltaT*(1:numSim), tempOverTime);
           title("Temperature over time");
114
           xlabel("Time");
115
           ylabel("Temperature");
116
           ylim([0 inf]);
117
           grid on
118
```

The temperature plot shows that the temperature remains constant at 300K throughout the simulation as expected.

2. Collisions with Mean Free Path (MFP)

In this part, the simulation program from part 1 was updated to calculate the actual Mean Free Path and mean time between collisions of the electrons in the system. The codes for part 2 are in the folder named "Q2", which contains the following files:

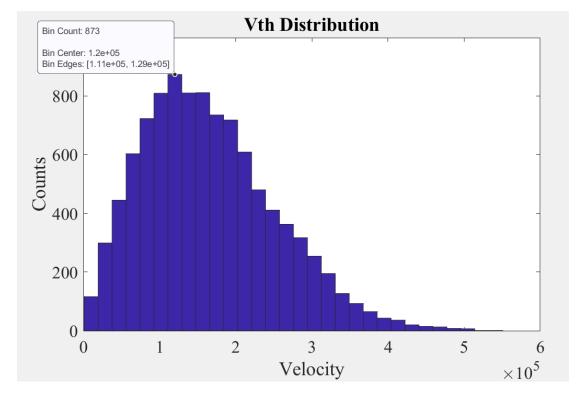

- AddElectrons.m Function that adds electrons randomly in the region
- globalVars.m File that groups the constants used in the simulation
- MD_Q2.m Entry point script for the simulation for part 2
- PlotPoint.m Function that plots the trajectories of the electrons
- plotTempDistribution.m Function that plots the initial temperature distribution
- tempDisplay.m Function that displays the temperature map
- 1. Assign a random velocity to each of the particles at the start. To do this you can use a Maxwell-Boltzmann distribution for each velocity component. Ensure that the average of all the speeds will be v_{th} . Plot the distribution in a histogram (Matlab 'hist' function).

The AddElectrons() function was updated to assign the random velocity to the particles with Maxwell-Boltzmann distribution for each velocity component.

To plot the v_{th} distribution of the system, a function named "plotVthDistribution()" was programmed to plot the distribution in a histogram.

```
MD_Q2.m × AddElectrons.m × plotVthDistribution.m ×
       % Helper function to plot the vth distribution
1 -
       % @ param nbins = number of bins
 2
 3 [
       function plotVthDistribution(nbins)
 4
       global vx vy
 5
       % Calculate the vth
 6
       Vth_data = sqrt(vx.^2 + vy.^2);
 7
 8
 9
       % Plot the velocity distribution histogram
10
       figure(3)
       hist(Vth_data, nbins);
11
       title("Vth Distribution")
12
       ylabel("Counts")
13
       xlabel("Velocity")
14
       end
15
```

The histogram shows that the bin center was roughly at $v_{th} = 1.2 \times 10^5$ m/s. This is similar to the expected value, which is $v_{th} = 187019.1244$ m/s.

```
>> MD_Q2
    "Mean path is 3.7404e-08"

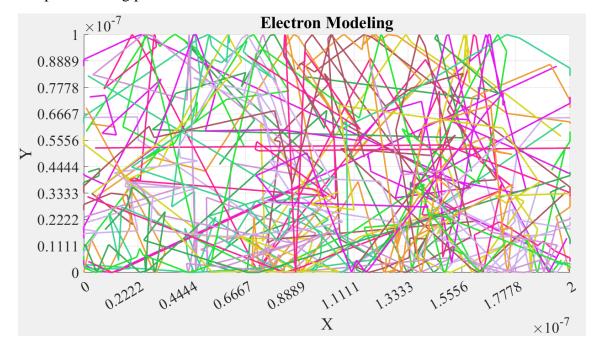

"vth = 187019.1244"
```

2. Model the scattering of the electrons using an exponential scattering probability: $P_{scat} = 1 - e^{-\frac{dt}{\tau_{mn}}}$, where dt is the time since the last timestep (and P_{scat} calculation), and τ_{mn} is the mean time between collisions. Use the τ_{mn} given above. At every time step (for every electron) use something like this: if $P_{scat} > rand()$ then the particle scatters. When the electron scatters re-thermalize its velocities and assign new velocities V_x , V_y from Maxwell-Boltzmann distributions. Refer to Figure 3 for a sample plot.

In the MD_Q2.m file, the P_{scat} was calculated before the main program loop.

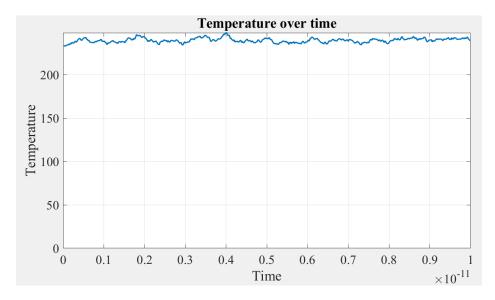

In the main program loop, the condition of $P_{scat} > rand()$ was checked for scattering. If the condition is met, the electron will be re-thermalized with new random velocity values.

The sample scattering plot is shown below.

3. What happens to the average temperature over time?

The following plot shows the average temperature over time, which remains roughly constant over time as expected.

In theory, the temperature should remain at roughly 300K over time. However, due to some unknown issue, the temperature from the simulation remains at roughly 250K instead of 300K.

4. Measure the actual Mean Free Path and mean time between collisions to verify your model.

To measure the actual Mean Free Path, the following variables are declared to hold the data for calculation.

When the electron scattered, the calculations for Mean Free Path and mean time between collisions are performed and the variables are updated to store the data.

```
MD_Q2.m × +
                   % Check for scattering
110
111
                   if ~bInvalid && Pscat > rand()
112
                      % Rethermalize
                       vx(iE) = sqrt(C.kb*T/C.mn).*randn();
113
                       vy(iE) = sqrt(C.kb*T/C.mn).*randn();
114
                       % Calculate the free path
115
                       deltaX = x(iE) - arrScatterPx(iE);
116
117
                       deltaY = y(iE) - arrScatterPy(iE);
                       totalFP = totalFP + sqrt(deltaX^2 + deltaY^2);
118
119
                       arrScatterPx(iE) = x(iE); % Update the previous scatter position
120
                       arrScatterPy(iE) = y(iE);
                       % Calculate the free time
121
                       totalFT = totalFT + simTime - arrScatterT(iE);
122
                       arrScatterT(iE) = simTime; % Update the previous scatter time
123
124
                       % Increment the count
                       countFPFT = countFPFT+1;
125
                   end
126
```

The actual Mean Free Path and mean time between collisions of the system are very similar to the expected results from calculation.

```
>> MD_Q2
   "Expected Mean free path is 3.7404e-08"

"vth = 187019.1244"

"Actual mean free path: 3.875e-08"

"Mean time between collision: 2.1221e-13"
```

	Actual Result	Expected Result
Mean Free Path	$3.875 \times 10^{-8} m$	$3.7404 \times 10^{-8} m$
Mean time between collision	0.21221 <i>ps</i>	0.2 <i>ps</i>

3. Enhancement

1. Basic Features and Analysis:

For this part, two box obstacles are added to the simulation environment. The codes for part 3 are in the folder named "Q3", which contains the following files:

- AddElectrons.m Function that adds electrons randomly in the region
- AddObstacles.m Function that adds rectangle obstacles
- globalVars.m File that groups the constants used in the simulation
- MD_Q3.m Entry point script for the simulation for part 3
- PlotPoint.m Function that plots the trajectories of the electrons
- plotTempDistribution.m Function that plots the initial temperature distribution
- tempDisplay.m Function that displays the temperature map
- (a) Add in the inner rectangle "bottle neck" boundaries as in Figure 4. There are a number of ways to do this. I did it by defining "boxes" that reflect particles and then adding a number of "boxes" to the region. You will need to be careful not to put electrons in the "boxes" at the start. You should also check that no electrons are leaking through the "boxes".

A function named "AddObstacles()" is implemented to add two rectangular obstacles.

Before the simulation loop, the rectangle boxes are drawn.

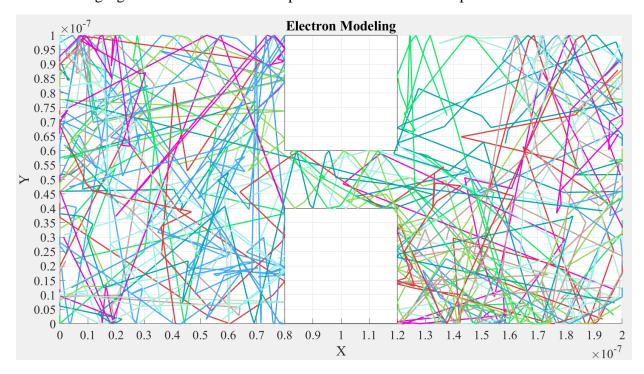

(b) Make all boundaries capable to be either specular or diffusive (ie re-thermalized).

A variable named "boundaryMode" is declared to hold the mode for the boundary.

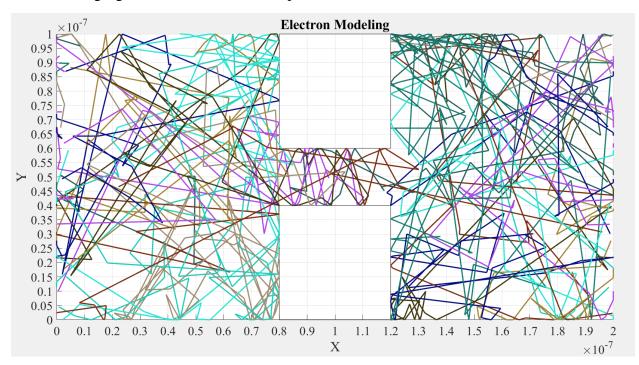

In the simulation loop, this variable is checked when an electron hit a boundary.

```
MD_Q3.m × +
                       % Check if the particle is inside a box
140
141
                       if (x(iE) \ge boxX1 \&\& x(iE) \le boxX2 \&\& y(iE) \ge boxY1 \&\& y(iE) \le boxY2)
142
                           bInvalid = true; %Invalid position
                           % Check for x position
143
144
                           if xp(iE) <= boxX1 % Coming from left side
145
                               x(iE) = boxX1;
                               % Check for boundary mode
146
147
                               if boundaryMode == 0 % Specular boundary
148
                                   vx(iE) = -vx(iE);
149
                               else % Diffusive boundary
                                   vx(iE) = -abs(sqrt(C.kb*T/C.mn).*randn()); % negative vx
150
151
152
                           elseif xp(iE) >= boxX2 % Coming from right side
                               x(iE) = boxX2:
153
                               % Check for boundary mode
154
155
                               if boundaryMode == 0 % Specular boundary
156
                                   vx(iE) = -vx(iE);
                               else % Diffusive boundary
157
158
                                   vx(iE) = abs(sqrt(C.kb*T/C.mn).*randn()); % positive vx
159
                               end
                           end
160
161
                           % Check for y position
162
                           if yp(iE) <= boxY1 % Coming from bottom
                               y(iE) = boxY1;
163
164
                               % Check for boundary mode
165
                               if boundaryMode == 0 % Specular boundary
                                   vy(iE) = -vy(iE);
166
                               else % Diffusive boundary
167
168
                                   vy(iE) = -abs(sqrt(C.kb*T/C.mn).*randn()); % negative vy
169
                           elseif yp(iE) >= boxY2 % Coming from top
170
171
                               y(iE) = boxY2;
172
                               % Check for boundary mode
                               if boundaryMode == 0 % Specular boundary
173
174
                                   vy(iE) = -vy(iE);
175
                               else % Diffusive boundary
                                   vy(iE) = abs(sqrt(C.kb*T/C.mn).*randn());  % positive vy
176
177
                               end
                           end
178
```

The following figure shows the simulation plot when boundaries are specular.

The following figure shows the simulation plot when boundaries are diffusive.

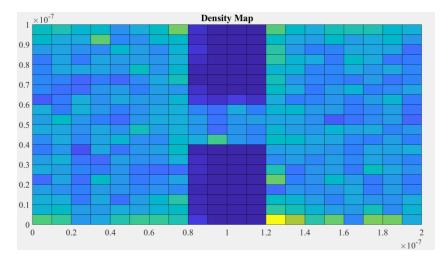

(c) Calculate an electron density map from the final electron positions.

To calculate the electron density map, a function named "tempDisplay()" was programmed.

```
MD_Q3.m × tempDisplay.m × +
       % This function generate a 2D temperature color plot
1 -
2
       % @param numGridX = number of grid in the x direction
3
                numGridY = number of grid in the y direction
                numE = number of electrons
4
5
                limitX = region limit on the x axis
                limitY = region limit on the y axis
6
       function tempDisplay(numGridX, numGridY, numE, limitX, limitY)
7
       % Global varibles use for temperature calculation
8
9
       global x y vx vy C
10
       global limits
11
       % Create the matrix for particle and total temperature
12
       matrixParticles = zeros(numGridX+1,numGridY+1);
13
       matrixTempTotal = zeros(numGridX+1, numGridY+1);
14
15
       % Calculate the deltaX and deltaY for each grid
16
17
       deltaX = limitX/numGridX;
       deltaY = limitY/numGridY;
18
19
20
       % Loop through all the electrons
21
       for iE = 1:numE
22
           % Calculate the x index (column) in the tempeture matrix
           indexCol = floor(x(iE)/deltaX)+1;
23
24
           indexRow = floor(y(iE)/deltaY)+1;
25
           % Calculate the velocity squared
26
27
           Vsqrt = sqrt(vx(iE)^2 + vy(iE)^2);
           % Calculate the temperature
28
29
           T = C.mn * Vsqrt^2 / (2*C.kb);
30
           % Increment the total temperature matrix
31
32
           matrixTempTotal(indexRow, indexCol) = matrixTempTotal(indexRow, indexCol) + T;
33
           % Increment the particle matrix
34
           matrixParticles(indexRow, indexCol) = matrixParticles(indexRow, indexCol) + 1;
35
36
       % Calculate the temperature matrix

       [X,Y] = meshgrid(linspace(0,limitX,numGridX+1), linspace(0, limitY, numGridY+1));
42
       % Plot the surface for temperature map
43
44
       figure(2)
       surf(X,Y,Temp);
45
       view(0,90); % view from the top
46
47
       title("Temperature Map")
48
       % Plot the surface for density map
49
       figure(5)
50
       surf(X,Y, matrixParticles);
51
52
       view(0,90); % view from the top
53
       title("Density Map")
54
55
       end
```

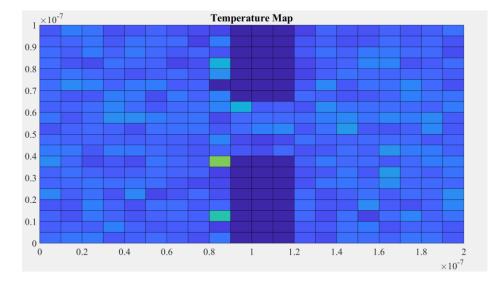

The electron density map was generated by grouping the electrons into a particle matrix and plot the density using the surf() function in MATLAB, which plotted a colored 3-d surface. The 2-D density map is then obtained by viewing on top from the surface.

It should be noted that the left-side edges of the two boxes region are not colored completely blue. This is because the grouping algorithm grouped all the electrons inside a square to the bottom left point of the square, and each square is colored based on the value at the bottom left point. Therefore, the electrons on the left-side edges of the boxes will be grouped to the left side. This similar principle also explained why the color of the bottom edge of the top box is not completely blue.

(d) Calculate a temperature map and display with colors.

The temperature map is calculated inside the "tempDisplay()" function. It was calculated by dividing the total temperature map by the density map. The following figure shows the temperature map.

2. Complete one of the following two tasks. Bonus marks for doing both.

3a. Curved Surfaces

(a) Curved Surfaces: Add curvilinear geometry into the simulation. An example would be a circle placed inside the region that reflects electrons. To do this you will need to (for each electron trajectory):

The codes for this part are in the folder named "Q3a", which contains the following files:

- AddElectrons.m Function that adds electrons randomly in the region
- AddObstacles.m Function that adds rectangle and circle obstacles
- findCircReflect.m Function that finds the reflected vector off the circle
- findLineCircIntersect Function that finds the intersecting point on the circle
- globalVars.m File that groups the constants used in the simulation
- MD_Q3a.m Entry point script for the simulation for part 3a
- PlotPoint.m Function that plots the trajectories of the electrons
- plotTempDistribution.m Function that plots the initial temperature distribution
- tempDisplay.m Function that displays the temperature map
- Determine if the electron has moved inside the circular inclusion

The condition for an electron has moved inside the circle is determined using the equation of the circle.

• If it has calculate the intersection of the trajectory with the circle.

A function named "findLineCircIntersect()" was programmed to find the intersection of the trajectory of the circle.

```
MD_Q3a.m × findLineCircIntersect.m × +
       % @param x1,y1 = first coordinate of the line segment
 2
 3
                 x2,y2 = second coordinate of the line segment
 4
                 cx,cy = center of the circle
 5
                 r = radius of the circle
 6
      % @return xn,yn = intersection point on the circle
       function [xn yn] = findLineCircIntersect(x1, y1, x2, y2, cx, cy, r)
 7
       % Declare some variable for easy reading
 8
 9
       xc1 = x1-cx;
10
       x12 = x2-x1;
11
       yc1 = y1-cy;
12
       y12 = y2-y1;
13
       a=x12^2+y12^2;
       b=2*(xc1*x12+yc1*y12);
14
15
       c=xc1^2+yc1^2-r^2;
```

```
16
17
       % First, let's find the parameter t for the parametrization of line segment
18
       t = (-b + sqrt(b^2-4*a*c))/(2*a);
19
       % Check that 0<=t<=1
20
       if t<0 || t>1
           % The other solution is the correct solution
21
           t = (-b - sqrt(b^2-4*a*c))/(2*a);
22
23
24
       % Next, find the intersection point
25
       xn = x1+t*x12;
26
       yn= y1+t*y12;
27
28
29
       end
```

- Then calculate the angle of incidence ϕ with respect to the normal of the surface.
- Finally, calculate the reflection direction using ϕ , assuming specular reflection (angle in equals angle out) and use this to determine a new position and velocity.

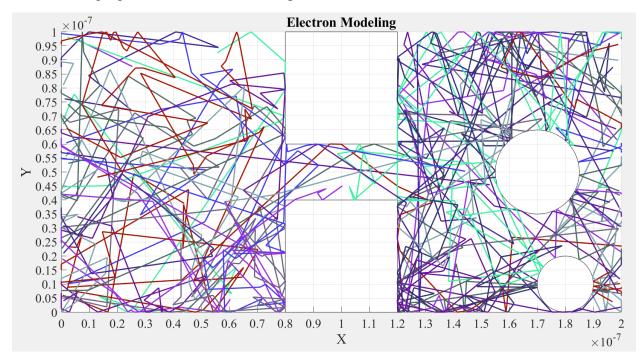

A function named "findCircReflect()" was programmed to find the reflection vector.

```
MD_Q3a.m × findLineCircIntersect.m × findCircReflect.m × +
       % Helper function to find the reflected vector from an incident vector
 2
       % @param xn,yn = point of intersection on the circle
3
                 vix, viy = incident vector
                 cx, cy = center of the circle
4
 5
       % @return vrx, vry = reflected vector
 6
       function [vrx, vry] = findCircReflect(xn, yn, vix, viy, cx, cy)
 7
       % Caclulate the normal vector
 8
       n = [xn-cx; yn-cy];
9
10
       n = n/norm(n); % Normalize
11
       % Incident vector
12
13
       d = [vix; viy];
       magD = norm(d); % magnitude of the incident vector
14
15
       % Calculate the reflected vector direction
16
       r = d - 2*dot(d,n)*n;
17
       theta = angle(r(1)+1j*r(2)); % angle for the reflected vector
18
19
       % Return the result
20
       vrx = magD*cos(theta);
21
22
       vry = magD*sin(theta);
23
24
       end
```

The code for implementing the reflection from the circle are shown in follow.

```
MD_Q3a.m × findLineCircIntersect.m × findCircReflect.m × +
193
                    % Step 3: Check for circles if not invalid yet
                    if ~bInvalid
 194
 195
                        for iCirc=1:numCirc
 196
                            % Retrieve the circle info
                            cx = circles(iCirc, 1);
197
                            cy = circles(iCirc, 2);
198
199
                            cr = circles(iCirc, 3);
                            % Check if the particle is inside the circle
 200
 201
                            if (x(iE)-cx)^2 + (y(iE)-cy)^2 \leftarrow cr^2
                                bInvalid = true; % Invalid position
 202
                                % First, find the intersection point (xn, yn)
 203
                                xn=x(iE); % Default assume on the circle
204
205
                                yn=y(iE);
 206
                                if (x(iE)-cx)^2 + (y(iE)-cy)^2 < cr^2
 207
                                    [xn, yn] = findLineCircIntersect(xp(iE), yp(iE), x(iE), y(iE),cx,cy,cr);
 208
 209
                                % Second, update the current position to be that intersect point
                                x(iE) = xn;
 210
 211
                                y(iE) = yn;
                                % Third, find the reflected velocity vector
212
213
                                [vrx, vry] = findCircReflect(xn,yn,vx(iE),vy(iE), cx, cy);
                                % Finally, updates the velocity vector
214
215
                                vx(iE) = vrx;
                                vy(iE) = vry;
216
                                % Break the loop
217
 218
                                break;
219
                            end
```

The following figure shows the simulation plot.

3b. Injection

(b) **Injection:** Model electron injection into a region:

The codes for this part are in the folder named "Q3b", which contains the following files:

- AddElectrons.m Function that initializes electrons with invalid electrons positions
- AddObstacles.m Function that adds rectangle and circle obstacles
- findCircReflect.m Function that finds the reflected vector off the circle
- findLineCircIntersect Function that finds the intersecting point on the circle
- globalVars.m File that groups the constants used in the simulation
- MD_Q3b.m Entry point script for the simulation for part 3b
- PlotPoint.m Function that plots the trajectories of the electrons
- plotTempDistribution.m Function that plots the initial temperature distribution
- tempDisplay.m Function that displays the temperature map
- i. Do not have any electrons present at the beginning.

The "AddElectrons()" is modified to initialize electrons with invalid electrons positions and zero velocities.

```
MD_Q3b.m × AddElectrons.m × +
      % This function add a bunch of electrons in a given region randomly for Q3b
      % @param numE = number of electrons
3
               region = region for the electrons
      function AddElectrons(numE, region)
4 -
5
       global x y % arrays for current electron positions
6
      global xp yp % arrays for previous electron positions
7
      global vx vy % arrays for current electron velocities
8
9
      % Create the arrays for electrons locations
      x = -10*ones(1, numE);
10
      y = region.y/2 * ones(1, numE);
11
12
      % Create the arrays for previous electron positions
13
14
      xp = x;
15
      yp = y;
16
      % Create arrays for velocity
17
18
      vx = zeros(1, numE);
19
      vy = zeros(1, numE);
20
      end
21
```

ii. Introduce them during the simulation from the left side with a positive v_x – derived from a thermalized velocity within a small central region.

Inside the simulation loop, the electrons are introduced by adjusting the position and thermalizing the velocity.

```
MD_Q3b.m × AddElectrons.m ×
           % Loop for simulation
94
95
           for iSim = 1:numSim
               % Check for create electron
96
97
               if mod(iSim, deltaSimCreateE) == 0
                   % Introduce an electron
98
99
                   x(iCreateE) = 0;
                   vx(iCreateE) = abs(sqrt(C.kb*T/C.mn).*randn());  % Positive vx
100
                   vy(iCreateE) = sqrt(C.kb*T/C.mn).*randn();
101
                   iCreateE = iCreateE+1;
102
103
               end
```

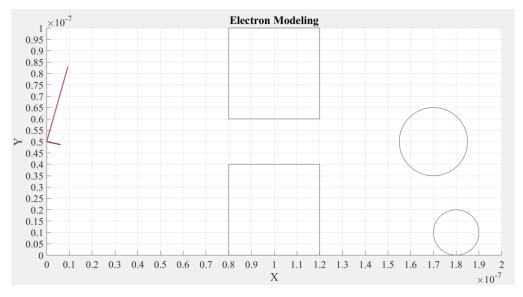

iii. Turn off the periodic BC conditions in x.

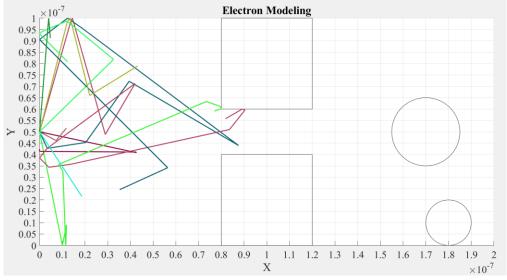

The periodic boundary conditions in x are changed to closed boundary conditions.

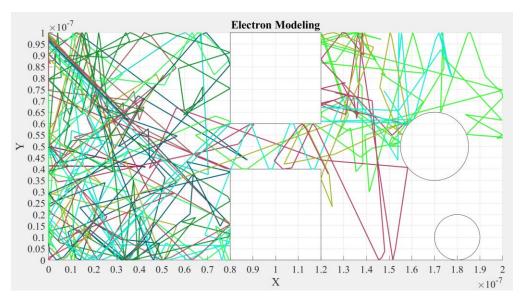

```
MD_Q3b.m × AddElectrons.m × +
123
                   % Step 1 - Check for boundaries
124
                   % Check for invalid x position
                   if x(iE) < 0 && x(iE) \sim = -10
125
126
                       bInvalid = true;
                       x(iE) = 0;
127
                       % Check for boundary mode
128
                       if boundaryMode == 0 % Specular boundary
129
130
                            vx(iE) = -vy(iE);
131
                       else % Diffusive boundary
                            vx(iE) = abs(sqrt(C.kb*T/C.mn).*randn());  % positive vx
132
133
                   elseif x(iE) >= Region.x
134
                       bInvalid = true;
135
136
                       x(iE) = Region.x;
137
                       % Check for boundary mode
                       if boundaryMode == 0 % Specular boundary
138
139
                           vx(iE) = -vx(iE);
                       else % diffusive boundary
140
                            vx(iE) = -abs(sqrt(C.kb*T/C.mn).*randn()); % negative vx
141
142
                       end
143
                   end
```

- iv. Investigate turning on and off scattering and adding boxes.
- v. Play with the initial value of v_x and v_y .

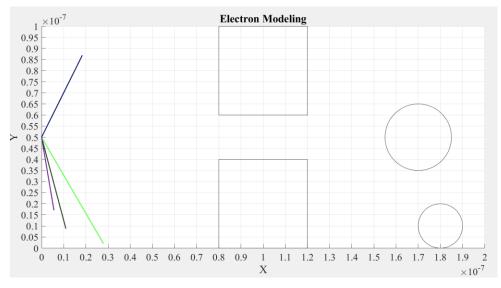

The following figures shows the simulation plots when the scattering is turned on.

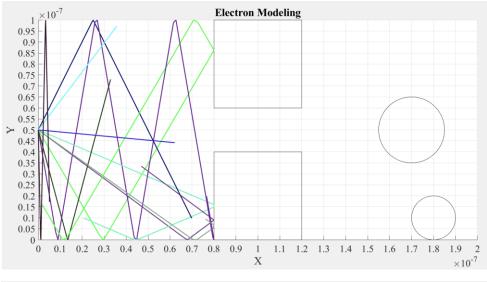

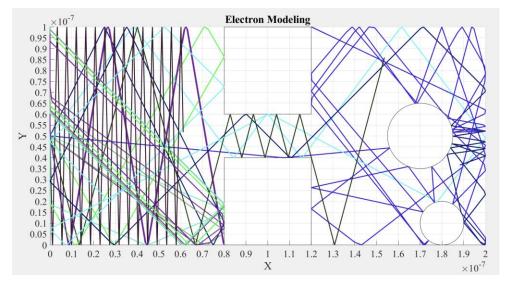

The following figures shows the simulation plots when the scattering is turned off.
